MICROBIAL CONSORTIA FROM RESIDENTIAL WASTEWATER FOR BIOREMEDIATION OF PHENOL IN A CHEMOSTAT

NORHANI JUSOH* & FIRDAUSI RAZALI2

Abstract. The study aimed at evaluating the potential of employing microbial consortia from residential wastewater to degrade phenol, a common industrial pollutant. The consortia was subjected to high shock loads and different levels of phenol in continuous cultures. In the shock load study with 1000 ppm phenol in a 1.5 litre working volume chemostat, the culture with prior acclimatization to phenol demonstrated 17 times higher affinity towards phenol (i.e. $K_s = 173$ ppm). This resulted in double growth rate ($\mu_{\text{max}} = D = 0.04 \text{ h}^{-1}$) compared to non-acclimatized culture. However, the levels of phenol reduction in both cases were almost identical, approximately 60%. This indicated that the performance of different types of bacteria present in the non-acclimatized culture which was comparable to the acclimatized culture although with less number of microbe types. The effects of two loading concentrations, namely 200 ppm and 1000 ppm were examined at constant dilution rate of 0.02 h$^{-1}$. The feeding of 200 ppm exhibited 97% of phenol reduction in comparison to only 57% of 1000 ppm. This result reconfirmed the inhibitory effect of phenol reduction at concentration above 500 ppm as previously determined in batch culture. The study has successfully established key operating parameters and provided a useful guideline for future up-scaling studies and site trials.

Keywords: Acclimatization, continuous, degradation, phenol, residential wastewater

Abstrak. Kajian ini bertujuan menilai potensi penggunaan konsortium mikrob dari air sisa buangan kediaman untuk penguraian fenol, pencemar umum daripada industri. Konsortium tersebut diuji dengan muatan mengejut dan kepekatan fenol yang berbeza di dalam kultur selanjur. Dalam uji kajian, kultur yang teradaptasi menunjukkan afiniti terhadap fenol 17 kali ganda lebih tinggi ($K_s = 173$ bpj) dan mengandakan kadar pertumbuhan ($\mu_{\text{max}} = D = 0.04 \text{ j}^{-1}$) berbanding kultur yang tidak teradaptasi. Pengurangan fenol untuk kedua-dua kes adalah hampir sama iaitu lebih kurang 60%. Penguraian oleh pelbagai jenis bakteria yang terdapat di dalam kultur yang tidak teradaptasi adalah setanding dengan yang teradaptasi walaupun dengan bilangan jenis bakteria yang lebih rendah. Kesan dua kepekatan masukan iaitu 200 bpj dan 1000 bpj telah dikaji pada kadar pencairan malar 0.02 j$. Suapan pada kepekatan 200 bpj memberikan pengurangan sebanyak 97% berbanding hanya 57% untuk kepekatan 1000 bpj. Keputusan ini telah menyokong keputusan kesian refkasi pada kepekatan yang melebihi 500 bpj seperti yang diperolehi dalam kultur kelompok sebelum ini. Kajian ini telah berjaya mengenali pasti parameter yang penting untuk penguraian fenol dan amat berguna untuk skala yang lebih besar pada masa depan dan juga sebagai percubaan di tapak industri.

Kata kunci: Adaptasi, air sisa buangan kediaman, fenol, penguraian, selanjur

1.0 INTRODUCTION

Phenol at high concentration is widely known as environmental pollutants due to commonly encountered in industrial effluents that include plastics manufacturing (600 – 2000 ppm), petrochemical manufacturing (50 – 600 ppm) and stocking production (6000 ppm) [1]. Efficient treatments of these wastewaters have been conducted by using several technologies including adsorption onto different matrices, solvent extraction, chemical oxidation and irradiation [2]. However, the existing removal methods have the inherent drawbacks due to the tendency of the formation of secondary toxic materials [3], complexity, and high cost of treatment [4]. Thus, in some cases, biological treatment has turned out to be a favourable alternative for phenol degradation.

Phenol degradation has been extensively investigated using variety of microorganisms including *Pseudomonas* sp. [3-7], *Rhodococcus* sp. [8], *Candida tropicalis* [9, 10] and *Acinetobacter* sp. [11]. Previous studies have shown that biodegradation of organic chemicals by using pure cultures usually can produce toxic intermediates. This problem may be overcome by the use of mixed cultures that have a wider spectrum of metabolic properties [5]. Therefore, in this study, mixed culture from residential wastewater was used as source of microorganisms to degrade phenol. Residential wastewater has been chosen because it contains diversify microorganisms as a result of wide variety of growth mediums including organic and inorganic matters as well as phenol substances. Phenol is released into residential wastewater as a product of metabolism in the urine and feces and phenol content in urine vary within the range of 5 to 55 mg/L [12].

In this work, phenol biodegradation was carried out in continuous culture and this mode closely mimics the real industrial processes. The objective of this work is to investigate the effect of acclimatization of cultures on continuous biodegradation with shock loading of phenol, and also to examine the tolerance of the microbial consortia towards inconsistent phenol, concentrations. The ability of acclimatized microbes to tolerate the shock load of phenol has been investigated since acclimatization stage was proved to overcome substrate inhibition problems that usually occurred in biodegradation at high concentration of phenol [13]. This is because certain enzymes in the microorganisms are induced during acclimatization stage, therefore, these microbes are available for next metabolism reaction [14].

2.0 MATERIALS AND METHODS

2.1 Experimental Setup

Batch and continuous biodegradations were performed in a bioreactor (B.BRAUN, Germany) with 1.5 litres working volume. The aeration rate was changed manually
to maintain the oxygen concentration at approximately 400 ppm. For continuous mode, an external multi channel pump (Cole Parmer, USA) was used to feed in the nutrient and to pump out the effluent from the bioreactor.

2.2 Culture and Media

Samples of wastewater were obtained from a local residential wastewater treatment plant and used as a source of the mixed culture. The culture was then enriched with LB medium that consists of 5 g/L yeast extract (CONDA, Spain), 10 g/L tryptone (CONDA, Spain), 15 g/L glucose (Sigma Chemical Co., USA) and 5 g/L sodium chloride (NaCl) (MERCK, Germany).

2.3 Acclimatization

Acclimatization of mixed cultures was carried out in bioreactor containing enriched microorganisms that was operated in batch mode with the addition of phenol at concentration level of 1000 ppm. The acclimatization stage has been carried out until complete removal of phenol.

2.4 Phenol Degradation

For the shock load study, 1000 ppm of phenol (Scharlau Chemie S.A, Spain) was incrementally supplied at 0.5, 1.0, 1.4, 1.8, and 2.0 ml/min into 1.5 L of acclimatized culture. The ability to withstand shock load of phenol was compared between acclimatized and non-acclimatized microorganisms. In a separate study, phenol has been supplied at different influent concentration namely 200 ppm and 1000 ppm at a constant flow rate of 0.5 ml/min. No nutrients was added, and air was supplied continuously during biodegradation process.

2.5 Analytical Methods

The microorganism growth was determined by measuring the optical density (OD) at 600 nm. For simplicity, one unit of optical density was assumed to correspond to approximately 1 g/L of biomass cell. Phenol concentration was determined by calorimetric method [15]. For each measurement, 2 ml of the sample was added to 0.3 ml of sodium carbonate (200 g/l) and 0.1 ml of Folin-Ciocalteau reagent. The absorbance was measured at 750 nm after 1 hour of incubation. A standard curve was prepared with concentration ranges from 0.002 to 0.01 g/L. A series of mass balance calculation were calculated for all continuous biodegradation to determine the average phenol concentration if biodegradation did not occurred. The average calculated phenol concentration was then compared with average phenol concentration in the purpose to obtain percent of phenol reduction.
3.0 RESULTS AND DISCUSSION

The competency of the uncharacterized microbial consortia was evaluated in continuous cultures supplemented with phenol as carbon source. Figure 1 shows the acclimatization stage that resulted in nearly complete reduction of phenol (93%) within 14 days of degradation. This result is comparable with result found by Gonzalez et al. [4] with complete reduction of phenol after 10 days of degradation with initial concentration of 1000 mg/L by using pure cultures of *Pseudomonas putida* ATCC 17484. This result proved that, robust mixed culture from residential wastewater have comparable performances as defined pure culture. This acclimatized consortia then was used in continuous biodegradation with shock loading of phenol as shown in Figure 2 and successfully reduced 61% of phenol concentration. The OD decreased as dilution rate is increased. Previous study also obtained that cell concentration decreased with incremental in dilution rate (D) during continuous biodegradation of phenol [6]. As a comparison, an experiment has been performed to study continuous biodegradation without acclimatization stage and the result is shown in Figure 3. These non-acclimatized consortia have resulted in 67% of phenol reduction. Incremental loading rate has apparently decreased the stability of the continuous culture for both experiments. Microbes managed to degrade phenol at low dilution rates, namely 0.02 h\(^{-1}\) and 0.04 h\(^{-1}\). Further increase of dilution rate at 0.056 h\(^{-1}\) has resulted in a washout, and consequently increased the phenol level up to 200 ppm. Hensel and Straube [8] also observed that the stability of the system decreased with increasing dilution rate.

![Figure 1](image-url)  
*Figure 1*  Phenol degradation during acclimatization stage
We discovered that the critical dilution rate, $D_c$, of acclimatized culture was 0.04 h$^{-1}$, which was twice of non-acclimatized one, which was less than 0.02 h$^{-1}$. Table 1 summarized the kinetic data including substrate utilization constant ($K_s$), maximum specific growth rate ($\mu_{max}$) and yield factor ($Y_{x/s}$) of these experiments. The acclimatized culture also indicated 17 times lower saturation constant, $K_s$ (i.e. 173 ppm) than the non-acclimatized one. It is evident that the acclimatization step has significantly improved the microbe’s affinity towards phenol. Despite this, no significant difference of average percentage of phenol reduction was witnessed between both cultures at the end of the process. The most possible explanation is that the performance of different types of bacteria present in the non-acclimatized culture was comparable to the acclimatized one, but with less number of microbe types. This was confirmed by
an unpublished result in a separate study in our laboratory indicating the reduction from five types to only two of residential wastewater microbes after treatment with phenol. Although both non-acclimatization and acclimatization step have resulted in the same average of phenol reduction, improvements in survival rate and affinity level offer more advantages especially at lengthy continuous degradation process.

**Figure 3** Continuous biodegradation of non-acclimatized microorganisms

Inconsistent loading strength is a common phenomenon in the actual waste treatment sites. Investigation on varying loading concentration on the degradation kinetic may determine its maximum tolerance level. It is a well-known fact that most degradation obeys the first order kinetics, where the rate of reaction is a function to its initial concentration. The influence of phenol initial concentration
on the degradation kinetic was investigated firstly in batch, and then extended to continuous culture. Results in batch cultures at three different initial phenol concentrations, namely 200, 500, and 1000 ppm indicated that both degradation rate (i.e. 2.06 ppm/h) and specific growth rate (i.e. 0.035 h\(^{-1}\)) at 500 ppm phenol were at the highest, as shown in Table 2. Our data is apparently in agreement with previous study by Bandyophadyay et al. [3] that inhibitory effects of phenol as substrate have become predominant above concentration of 500 ppm of phenol by using *Pseudomonas putida* (MTCC 1194).

Figures 4 and 5 show a time-course profile of continuous phenol degradation with feeding concentration of 200 ppm and 1000 ppm, respectively. In continuous cultures at dilution rate of 0.02 per hour, the feeding of 200 ppm phenol gave 97% of phenol reduction in comparison to only 57% at 1000 ppm. This result shows the dependence of the effluent concentration on feed concentration. This observation matched well with a published data reported by Beltrame et al. [19] found that substrate concentration in the effluent increases proportionally to feed...
concentration. This kinetic anomaly is due to substrate inhibition by some secondary reaction products. However, the total phenol removal rate (defined as difference of phenol concentration between influent and effluent, multiplied by dilution rate) [20] at 1000 ppm was three time higher than at 200 ppm as shown in Table 3. Should higher loading concentration, i.e. 1000 ppm is unavoidable, lower dilution rates may compensate the harsh effect of phenol.

4.0 CONCLUSION

Acclimatization of microorganisms to phenol has improved microbe’s survival rate as well as affinity to the substrate. No significant improvement in phenol reduction shown by acclimatized culture compared to non-acclimatized one. Phenol concentrations above 500 ppm might inhibit the culture and resulted in lower rate of phenol reduction. This is true for both batch and continuous modes. In short, in this study we have successfully established key operating parameters (i.e. dilution rates, maximum specific growth rate and feeding concentration) for phenol degradation using microbes from wastewater and provide useful guideline for future scaling works.

ACKNOWLEDGEMENTS

We would like to thank all technicians and postgraduates in the Department of Bioprocess Engineering for their contributions to this research. We also like to express our gratitude to the UTM’s Research Management Centre for financing this study through a short term grant (Vot. 75200) as well as providing the scholarship.
