1.0 INTRODUCTION

Tensors can be considered a generalization of matrices. They are represented as a multidimensional array of numbers. The application of real rectangular tensors, amongst others, include part of the strong ellipticity condition problem within solid mechanics and entanglement problem within quantum physics [1-6].

Most properties of tensors are generalized from matrices. We have seen in these past few years that the study of the spectral radius for tensors has developed a great interest. Chang, Qi and Zhou [7] introduced the class of the real rectangular tensor, and have presented a method for calculating the largest singular value of a nonnegative rectangular tensor. This method was originally used in order to find the largest eigenvalue of a nonnegative matrix [8, 9]. Later the method was extended by Ng, Qi and Zhou [10] for square tensors and most recently for rectangular tensors [7]. Zhou, Caccetta and Qi [11] improved the method in [7] and have shown that the algorithm converges for irreducible nonnegative rectangular tensors.

The largest singular value problems can also be solved through the use of metaheuristics optimization algorithms. Some of the novel recent works within the field of metaheuristics include the Enhanced Leader PSO [12,13], the Brainstorm Optimization Algorithm [14], the Chaotic-Based Big Bang-Big Crunch Algorithm [15], and the Chaotic Bat Swarm Optimization [16].

However the convergence of the method presented in [11] is limited to only irreducible nonnegative rectangular tensors. It is unknown whether the method is also convergence for a wider class of tensors.

There are two objectives of this paper. The first objective is to prove that the method presented in the study of Zhou et al. [11] for finding the largest singular value is convergent when the tensor is a weakly irreducible nonnegative rectangular tensor, and the second is to prove that the rate of convergence for the method in the study [11] is Q-
linear, when the tensor is a weakly irreducible nonnegative rectangular tensor.

In this paper, we introduce the class of the weakly irreducible rectangular tensor, which is a wider class than the irreducible rectangular tensor. We then establish the convergence of the method in the study of Zhou et al. [11] for weakly irreducible nonnegative rectangular tensors, and its rate of convergence. This research intends to contribute to the convergence properties for the method of finding the largest singular value of rectangular tensors.

In Section 2, we provide definitions and theorems to be used later. In Section 3, it is proved that the algorithm given in [11] converges for weakly irreducible nonnegative rectangular tensors. In Section 4, it is proven that the algorithm in [11] has Q-linear convergence, and lastly in Section 5 this paper is concluded.

2.0 PRELIMINERIES

Let $\mathbb{R}$ be the real field, let $\mathbb{R}_+$ be the set of nonnegative numbers, and let $\mathbb{R}_+$ be the set of positive numbers. Let $p,q,m,n \in \mathbb{R}_+$ and $m,n \geq 2$. We can say $A$ is a real $p,q$-th order $m \times n$ dimensional rectangular tensor, where:

$$A = \left(A_{i_1 \ldots i_p j_1 \ldots j_q}ight)_{i_1 \ldots i_p \leq m, 1 \leq j_1 \ldots j_q \leq n}$$

(1)

We call $A$ a nonnegative rectangular tensor if $A_{i_1 \ldots i_p j_1 \ldots j_q} \geq 0$. When $m = n$, $A$ is a square tensor and when $p = 1, q = 1$, matrix $A$ is an $m \times n$ rectangular matrix.

The singular value of rectangular tensors is comparable to the eigenvalue of square tensors. Here we use the following definition for the singular value of rectangular tensors. See e.g. [7]. Let $(Ax^x^y^z) \in \mathbb{R}^n$, where:

$$\left(Ax^x^y^z\right) = \sum_{i_1 \ldots i_p \leq m} \sum_{j_1 \ldots j_q \leq n} A_{i_1 \ldots i_p j_1 \ldots j_q} x_{i_1} \ldots x_{i_p} y_{j_1} \ldots y_{j_q},$$

$i = 1, \ldots, m$, and let $(Ax^x^y^z) \in \mathbb{R}^n$, where:

$$\left(Ax^x^y^z\right) = \sum_{k_1 \ldots k_p \leq m} \sum_{l_1 \ldots l_q \leq n} A_{k_1 \ldots k_p l_1 \ldots l_q} x_{k_1} \ldots x_{k_p} y_{l_1} \ldots y_{l_q},$$

$j = 1, \ldots, n$. We set $M = p + q$ and $N = m + n$. Let

$$Ax^x^y^z = \lambda x^x^y^z, \quad Ax^x^y^z = \lambda x^x^y^z$$

(2)

We call $\lambda \in \mathbb{C}$ a singular value of $A$, where $\mathbb{C}$ is the set of complex numbers. We can say $x \in \mathbb{C}^n \setminus \{0\}$ and $y \in \mathbb{C}^n \setminus \{0\}$ are left and right eigenvectors of $A$, paired with the singular value $\lambda$, if $\lambda, x$ and $y$ satisfy the equation (2). The following are some preliminaries:

Theorem 1 (p.20,[17]). An $n \times n$ complex matrix $A$ is irreducible if and only if its directed graph $G(A)$ is strongly connected.

Theorem 2 (p.51,[17]). Let $A$ be an irreducible matrix, with $G(A)$ being the associated directed graph. If the greatest common divisor (gcd) of the lengths of its closed paths is equal to one, then $A$ is primitive.

The converse of Theorem 2 also holds.

Theorem 3 (Chapter 2.[17]). If $A$ is an irreducible nonnegative square matrix, then:

(i) the spectral radius $\rho(A)$ is an eigenvalue;

(ii) there exists a nonnegative vector $x_0 > 0$, such that $Ax_0 = \rho(A) x_0$;

(iii) (uniqueness) if $\lambda$ is an eigenvalue with a nonnegative eigenvector, then $\lambda = \rho(A)$;

(iv) $\rho(A)$ is a simple eigenvalue of $A$;

(v) if $\lambda$ is an eigenvalue of $A$, then $|\lambda| \leq \rho(A)$.

Furthermore, if a nonnegative matrix $A$ is primitive, then $\rho(A) > |\lambda|, \forall \lambda \in \sigma(A) \setminus \{\rho(A)\}$, where $\sigma(A)$ is the spectrum of $A$.

Corollary 1 [18]. An irreducible matrix with a nonzero main diagonal is primitive.

Proposition 1 [19,20]. The spectral radius of an $n \times n$ matrix $A$ is characterized by the equality

$$\rho(A) = \inf_{\|x\| = 1} \|Ax\|$$

where $\|x\|$ denotes the set of all possible spectral norms of $A$. For any $\epsilon > 0$, there exists a spectral norm $\|x\| \in N$ such that $\|Ax\| \leq \rho(A) + \epsilon$.

For any $j = 1, \ldots, n$, let $A_j = \left(A_{i_1 \ldots i_p j_1 \ldots j_q}\right)$ be a $p$-th order, $m$ dimensional square tensor. For any $i = 1, \ldots, m$, let $A_j = \left(A_{i_1 \ldots i_p j_1 \ldots j_q}\right)$ be a $q$-th order $n$ dimensional square tensor. In this paper we consider all polynomials to be monotone and homogeneous.

Definition 1 [7, 11]. A nonnegative rectangular tensor $A$ is irreducible if all the square tensors $A_j = \left(A_{i_1 \ldots i_p j_1 \ldots j_q}\right)$, $j = 1, \ldots, n$, and $A_i = \left(A_{i_1 \ldots i_p j_1 \ldots j_q}\right)$, $i = 1, \ldots, m$, are irreducible.

Let $A$ be a nonnegative $p,q$-th order $m \times n$ dimensional rectangular tensor. The graph $G(A) = (V, E(A))$ is the associated graph of tensor $A$.

The vertex set is $V = \bigcup_{j=1}^{n} V_j$, with $V_j = \{1, \ldots, m\}$ for $j = 1, \ldots, p$ and $V_j = \{1, \ldots, n\}$ for
Theorem 4 [11]. If \( A \) is an irreducible nonnegative rectangular tensor of the order \( p,q \) and the dimension \( m \times n \), then there exists \( \mu_0 > 0 \), \( x_0 \in \mathbb{R}^p_+ \) and \( y_0 \in \mathbb{R}^q_+ \) such that:

\[
B_i(x_0, y_0) = \mu_0x_0^{[M-i]}, \quad B_i(x_0, y_0) = \mu_0y_0^{[M-i]}.
\]

Moreover, \( \mu_0 \) satisfies the following equalities:

\[
\mu_0 = \min_{(x,y) \in \mathbb{R}^p_+ \times \mathbb{R}^q_+} \max_{i,j} \left( \frac{B_i(x, y)}{x^{[M-i]}} \cdot \frac{B_j(x, y)}{y^{[M-j]}} \right)
\]

\[
= \max_{(x,y) \in \mathbb{R}^p_+ \times \mathbb{R}^q_+} \min_{i,j} \left( \frac{B_i(x, y)}{x^{[M-i]}} \cdot \frac{B_j(x, y)}{y^{[M-j]}} \right)
\]

and \( \mu_0 - \rho \) is the largest singular value of the rectangular tensor \( A \).

3.0 WEAKER CONVERGENT CONDITION

An algorithm for finding the largest singular value of an irreducible nonnegative rectangular tensor was proposed by Chang et al. [7]. Later, it was updated by Zhou et al. [11]. In this section, we will prove that the algorithm is convergent for weakly irreducible nonnegative rectangular tensors.

Algorithm 1 [11]

**Step 0:** Choose \( \rho > 0, x^{(0)} > 0 \) and \( y^{(0)} > 0 \). Set \( k = 1 \).

**Step 1:** Calculate \( \xi^{(k)} = B_i(x^{(k)}, y^{(k)}) \) and \( \eta^{(k)} = B_j(x^{(k)}, y^{(k)}) \). Let

\[
\mu_k = \min_{\xi^{(k)}, \eta^{(k)}} \max \left( \frac{\xi^{(k)}}{x^{(k)}} \cdot \frac{\eta^{(k)}}{y^{(k)}} \right)
\]

\[
\bar{\mu}_k = \max_{\xi^{(k)}, \eta^{(k)}} \min \left( \frac{\xi^{(k)}}{x^{(k)}} \cdot \frac{\eta^{(k)}}{y^{(k)}} \right)
\]

**Step 2:** If \( \mu_k = \bar{\mu}_k \), then stop. Otherwise, compute

\[
x^{(k+1)} = \left( \frac{\xi^{(k)}}{x^{(k)}} \right)^{\frac{1}{M-1}} \quad \text{and} \quad y^{(k+1)} = \left( \frac{\eta^{(k)}}{y^{(k)}} \right)^{\frac{1}{M-1}}.
\]

replace \( k \) with \( k+1 \) and go to Step 1.

Let \( \mu_0 = \bar{\mu}_k \). The largest singular value of \( A \) is \( \mu_0 - \rho \). Zhou et al. [11] have shown that this algorithm is convergent, if \( A \) is an irreducible nonnegative rectangular tensor. We will now show that Algorithm 1 is convergent if \( A \) is a weakly irreducible nonnegative rectangular tensor.

We define the polynomial map

\[
P(z) = \begin{bmatrix} Az & y \\ y & y \end{bmatrix},
\]

where \( N = m + n \), \( y = \begin{bmatrix} x \\ y \end{bmatrix} \). Let \( P \) be a polynomial with degree, \( d > 1 \). Suppose that the coefficient of each monomial in \( P \) is nonnegative. The associated graph of \( P \) is the directed graph \( G(P) = (V, E(P)) \), where the vertices \( V = \{1, 2, ..., N\} \) and the edge \( (i, j) \in E(P) \) if the coefficient of variable \( z_j \) appears in the expression of \( P \).

Definition 2: Let \( P = (P_1, ..., P_n)^T: R^N_+ \rightarrow R^N_+ \) be a polynomial map, where each \( P_i \) is a homogeneous polynomial of the degree \( d \geq 1 \) with nonnegative coefficients. We call \( P \) weakly irreducible if \( G(P) \) is strongly connected. If the directed graph \( G(P) \) is strongly connected, and the graph common divisor (gcd) of the lengths of its circuits is equal to one, then we say \( P \) is weakly primitive.

Another way to check the gcd of a graph’s lengths of is to observe the diagonal of its associated matrix. An irreducible matrix has a nonzero main diagonal entry and if only if the associated directed graph has a loop, a closed path with length equals to one.

We can show that \( P \) is weakly primitive by proving that the associated matrix of its graph is primitive. Let \( M(G(P)) \) be the associated matrix of graph \( G(P) \). We can say that \( M(G(P)) \) is primitive if the graph is strongly connected, and if the gcd of its lengths is equal to one.
Definition 3: A rectangular tensor $A$ is weakly irreducible if $P$ is weakly irreducible.

Let $B(z) = \begin{pmatrix} Ax^{-1}y^0 + \rho x^{[M-1]} \\ Ax^{-1}y^0 + \rho y^{[M-1]} \end{pmatrix}$ and let $I(z) = \begin{pmatrix} \rho x^{[M-1]} \\ \rho y^{[M-1]} \end{pmatrix}$.

Hence we have $B(z) = P(z) + I(z)$. Now we prove that Algorithm 1 is convergent, if tensor $A$ is weakly irreducible.

We can now present our results for this section.

Lemma 1: If $A$ is a weakly irreducible nonnegative rectangular tensor with the order $p, q$ and the $m \times n$ dimension, then $B(z)$ is a weakly primitive polynomial.

Proof. Since $A$ is weakly irreducible then $P(z)$ is a weakly irreducible polynomial. By Definition 2, the graph of $P(z)$, $G(P(z))$ is strongly connected. By Theorem 1, the matrix of $G(P(z))$ is irreducible. We know that $G(I(z))$, the graph of $I(z)$, has a self-loop at each vertex. Therefore the matrix of $G(I(z))$ is a diagonal matrix. Hence, by Corollary 1, the matrix of $G(B(z))$ is primitive. By Theorem 2, $G(B(z))$ is strongly connected, and has a gcd that is equal to one. This implies by Definition 2 that $B(z)$ is a weakly primitive polynomial.

The following theorem is the main result of this paper.

Theorem 6. Let $A$ be a weakly irreducible rectangular tensor of the $p, q$-th order and the $m \times n$ dimension. Suppose that $(\mu_0, x_0, y_0)$ is the solution of equation [5]. Then, Algorithm 1 yields the value of $\mu_0$ through a finite number of steps, or generate two convergent sequences $\{\mu_k\}$ and $\{\bar{\mu}_k\}$, both of which converge to $\mu_0$. The largest singular value of $A$ is $\mu_0 - \rho$ .

Proof. By Lemma 1 and Corollary 5.1 [21], Algorithm 1 converges when the rectangular tensor $A$ is weakly irreducible.

4.0 RATE OF CONVERGENCE

In this section, we will show that Algorithm 1 has $Q$-linear convergence, when $A$ is a nonnegative weakly irreducible rectangular tensor of $p, q$-th order and $m \times n$ dimensional. We use the same argument as Zhou, Qi and Wu’s study [22].

Define:

$$D(z) = F(z)^{\frac{1}{M-1}}, \quad H(z) = \frac{D(z)}{\phi(D(z))},$$

where $\phi: R^N \rightarrow R$ is defined as:

$$\phi(z) = \sum_{i=1}^{N} z_i,$$

for any nonnegative $z \in R^N$. We can see that the sequence $\{z^{(k)}\}$ in Algorithm 1 is generated by

$$z^{(k+1)} = H(z^{(k)}), \quad k = 1, 2, ...,$$

and $\phi(z^{(k)}) = 1$ for all $k = 1, 2, ...$ .

Lemma 2. Let $\mu_0, x_0$ and $y_0$ be as in Theorem 6 and let $H'(z_0)$ be the Jacobian of the function $H$ at $z_0$. Then, $\rho(H'(z_0)) < 1$.

Proof. Let $\mu_0$ be the largest singular value of $B$ and $z_0$ be the corresponding eigenvector. We have $H(z_0) = D(z_0)/\phi(D(z_0))$. We want to show that:

$$\rho(H'(z_0)) = \rho \left( \frac{D'(z_0)\phi(D(z_0)) - D(z_0)\phi'(D(z_0))}{\phi'(D(z_0))} \right) < 1.$$

We already have $F(z_0) = B(z_0) + \mu_0 x_0 y_0$ and $\phi(z_0) = 1$.

Hence, $D(z_0) = F(z_0)^{\frac{1}{M-1}} = \mu_0^{\frac{1}{M-1}}$. Let $\mu_0 = \mu_0^{\frac{1}{M-1}}$, so we have $D(z_0) = \mu_0 z_0$.

Now we compute $D'(z_0)$, i.e. the Jacobian of $D$ at $z_0$. Let

$$D(z_0) = D(z_0)^{\frac{1}{M-1}} \begin{pmatrix} (F_1(z_0))^{\frac{1}{M-1}} \\ \vdots \\ (F_N(z_0))^{\frac{1}{M-1}} \end{pmatrix} = \frac{1}{M-1} \begin{pmatrix} F_1(z_0) \ | \ F_2(z_0) \ | \ \ldots \ | \ F_N(z_0) \end{pmatrix} \forall F(z_0).$$

By the same method, we can get:

$$\forall \left( F(z_0)^{\frac{1}{M-1}} \right) = \frac{1}{M-1} \left( F(z_0)^{\frac{2-M}{M-1}} \right) \forall F(z_0), \quad i = 1, ..., N.$$

Thus the Jacobian of $D$ at $z_0$ is given below:

$$D'(z_0) = \nabla \left( F(z_0)^{\frac{1}{M-1}} \right) = \frac{1}{M-1} \begin{pmatrix} \nabla (F_1(z_0))^{\frac{1}{M-1}} \\ \vdots \\ \nabla (F_N(z_0))^{\frac{1}{M-1}} \end{pmatrix}.$$

\[
\begin{bmatrix}
\frac{1}{M-1}(F(z_0))^\top & 0 \\
\vdots & \ddots \\
0 & \frac{1}{M-1}(F_N(z_0))^\top
\end{bmatrix}
\begin{bmatrix}
\nabla F(z_0) \\
\nabla F_1(z_0) \\
\vdots \\
\nabla F_N(z_0)
\end{bmatrix}
= \text{diag}\left(\frac{1}{M-1}(F(z_0))^\top \right) F'(z_0).
\]
where \( \frac{1}{M-1}\text{diag}\left(\mu z_0^{(M-1)} \right) \) is a constant with \( \mu > 0 \), and \( z_0 \) is a positive vector. Therefore \( G(D'(z_0)) = G(F'(z_0)) \). For the graph of \( B \), by definition, there exists an edge between \( i \) and \( j \), if variable \( z_i \) appears in the expression of \( B \). Notice that the graph of \( B \) is similar to the graph of \( D' \). \( G(D'(z_0)) = G(F'(z_0)) = G(B(z_0)) \). Lemma 1 states that \( B \) is weakly primitive, therefore, the graph of \( B \) is strongly connected. Hence the graph of \( D' \) is also strongly connected, and \( D' \) is therefore irreducible. The term \( I(z) \) in \( B \) ensures that the diagonal is nonzero, and that implies \( D' \) be primitive matrix. Since \( D'(z_0) \) is a primitive matrix, by Theorem 3, the eigenvalues \( \lambda_1, \lambda_2, \ldots, \lambda_N \) of \( D'(z_0) \) can be ordered as follows:
\[
\lambda_i = \rho(D'(z_0)) > \lambda_j \geq \lambda_k \geq \ldots > |\lambda_N|.
\]
For all \( i > 1 \), we expand \( D(z_0) \) about \( z_0 \) by using Taylor's Series, and obtains:
\[
\begin{align*}
\mu z_0 = D(z_0) \\
\mu z_0 = D(z_0) + D'(z_0)(z_0 - z_0) + o([z_0 - z_0]) \\
\mu z_0 = D(z_0) + (t-1)D'(z_0)z_0 + o(t-1) \\
(t-1)\mu z_0 = (t-1)D'(z_0)z_0 + o(t-1),
\end{align*}
\]
which implies that \( D'(z_0)z_0 = \mu z_0 \). Since \( D'(z_0) \) is a primitive matrix, and \( z_0 > 0 \), by referring to the Theorem 3, \( z_0 \) is an eigenvector of \( D'(z_0) \) associated with the largest eigenvalue \( \mu_1 = \lambda_1 \). Therefore, \( \phi(D(z_0)) = \phi(\mu z_0) = \mu_1 \).

We also have \( \phi(D(z_0)) = D(z_0) + D'(z_0) + \ldots + D_N(z_0) \), and \( \phi(D(z_0)) = D(z_0) + D'(z_0) + \ldots + D_N(z_0) = e D(z_0) \), where \( e \) is the row vector of ones with \( N \) dimension. From \( H(z_0) = D(z_0) / \phi(D(z_0)) \), and after some manipulations we attain:
\[
H'(z_0) = \frac{D(z_0) - z_0 e D(z_0)}{\mu_1}.
\]
Let \( S = D'(z_0) \) and \( Q = S - z_0 e S \). Therefore the above equation can be written as \( H'(z_0) = Q / \mu_1 \). Here let it be reminded that we want to prove that \( \rho(H'(z_0)) = \rho(Q / \mu_1) < 1 \). We can achieve this by showing that the spectral radius of \( Q \) is equal to \( |\lambda_1| \).

We can also show that the spectrum of \( Q \) is \( \{0, \lambda_2, \lambda_3, \ldots, \lambda_N\} \).

We have \( 1 = \phi(z_0) = (z_0) + \lambda_1 z_0 + \ldots + \lambda_N z_0 = z_0 \), so \( \lambda_1 = 1 \) and \( Q = S - z_0 e S \). \( Q e^\top = (S - z_0 e S)e^\top = 0 \). We can conclude that \( e^\top \) is an eigenvector of \( Q^e \), associated with the eigenvalue 0.

There are two possible cases of \( S^e \).

**Case 1:** The matrix \( S^e = D'(z_0)^e \) is diagonalizable, that is, \( S^e \) is semisimple. For \( i = 2,3, \ldots, N \), we assume \( S^e w = v w \), where \( w \) is an eigenvector of \( S^e \) that is associated with the eigenvalue \( v \). Suppose that the set of eigenvectors \( \{ w, w^2, \ldots, w^N \} \) is linearly independent.

We can write \( v z_0 w = z_0 w^2 = z_0 S^e w^e \), for \( i = 2,3, \ldots, N \).

We already have \( D'(z_0) z_0 = S z_0 = \mu z_0 \). So, \( z_0 z_0 = (\mu z_0) \), and \( z_0 z_0 = \mu z_0 \).

Hence, \( v z_0 w^e = z_0 S^e w^e = \mu z_0 w, \) \( v = \mu \) \( z_0 w^e = 0 \). So, for \( i = 2,3, \ldots, N \), it is either \( v = \mu \) or \( z_0 w^e = 0 \). However \( v = \mu \) for \( i = 2,3, \ldots, N \). Therefore \( z_0 w^e = 0 \).

Now we have \( Q^e w^e = (S - z_0 e S) w^e = S^e w^e = 0 \). Since we assume that \( S^e w = v w \), so then \( Q^e w^e = v w^e \). The vector \( w^e \) is an eigenvector of \( Q^e \) associated with the eigenvalue \( v \), for \( i = 2,3, \ldots, N \).

Now we prove that the set of eigenvectors of \( Q \), \( \{v^e, w^2, w^3, \ldots, w^N \} \) is linearly independent. Suppose that:
\[
\alpha_1 v^e + \alpha_2 w^2 + \ldots + \alpha_N w^N = 0, \tag{8}
\]
and \( v \neq 0 \) for \( i = 2,3, \ldots, p \) and \( v_j = 0 \) for \( j = p + 1, \ldots, N \).

We know that \( Q^e v^e = 0 \), and \( Q^e w^e = v w^e \) for \( i = 2,3, \ldots, N \). Adding these two equations on LHS and RHS respectively yield:
\[
Q^e v^e + Q^e w^2 + \ldots + Q^e w^N = 0 v^e + v w^2 + \ldots + v w^N.
\]

Now, substitute \( e^\top, w^2, w^3, \ldots, w^N \) with \( \alpha_1 e^\top, \alpha_2 w^2, \alpha_3 w^3, \ldots, \alpha_N w^N \) of equation (8) and obtain:
\[
\alpha_1 Q^e v^e + \alpha_2 Q^e w^2 + \ldots + \alpha_N Q^e w^N = 0 e^\top + v_1 w^2 + \ldots + v_N w^N.
\]

Now, substitute \( e^\top, w^2, w^3, \ldots, w^N \) with \( \alpha_1 e^\top, \alpha_2 w^2, \alpha_3 w^3, \ldots, \alpha_N w^N \) of equation (8) and obtain:
\[
\alpha_1 Q^e v^e + \alpha_2 Q^e w^2 + \ldots + \alpha_N Q^e w^N = 0 e^\top + v_1 w^2 + \ldots + v_N w^N.
\]

Since we consider the set \( \{w^2, w^3, \ldots, w^N\} \) to be linearly independent, we then get \( \alpha_1 = \alpha_2 = \ldots = \alpha_N = 0 \), and we can now write equation (8) as:
\[
\alpha_1 e^\top + \alpha_2 w^2 + \ldots + \alpha_N w^N = 0, \tag{10}
\]
\[ S^T (\alpha e^T + \alpha_1 v_1^T w_{p+1} + \ldots + \alpha_N w_N^T) = 0, \]
\[ S^T e^T + \alpha_{p+1} v_{p+1} w_{p+1}^T + \ldots + \alpha_N w_N^T = 0. \]
Since \( S^T w_j = v_j w_j \) for \( j = p+1, \ldots, N \), we then get
\[ \alpha_1 S^T e^T + \alpha_{p+1} v_{p+1} w_{p+1}^T + \ldots + \alpha_N w_N^T = 0. \]
Since \( v_j = 0 \) for \( j = p+1, \ldots, N \), it yields
\[ \alpha_1 S^T e^T = 0. \]
We then get \( \alpha_1 = 0 \) since \( \alpha_1 S^T e^T > 0 \) and \( S \) is diagonalizable. From equation (10), we have
\[ \alpha_{p+1} v_{p+1} w_{p+1}^T + \ldots + \alpha_N w_N^T = 0. \]
(11)
We know that the set \( \{ w_{p+1}, w_{p+2}, \ldots, w_N \} \) is linearly independent, so \( \alpha_{p+1} = \ldots = \alpha_N = 0 \). So we get \( \alpha_1 = \ldots = \alpha_N = 0 \). This means that the set \( \{ e^T, w_1, w_2, \ldots, w_N \} \) is linearly independent and the spectrum of \( Q \) is \( \{0, v_1, v_2, \ldots, v_N\} \).

**Case 2:** Consider that \( S^T \) is not diagonalizable or defective. We know that a defective matrix has less than \( N \) different eigenvalues. Assume that \( S^T \) has \( q < N \) different eigenvalues where \( v_i = \mu_i, v_1, \ldots, v_q \), and these eigenvalues can be written as follows:
\[ v_i = \mu_i > |v_i| > |v_j| > \ldots > |v_q|. \]
(12)
So, \( S^T \) has the form \( S^T = XAX^{-1} \), where the \( J = \text{diag} \{ J_1, J_2, \ldots, J_q \} \) is in a canonical form. Suppose that the square matrices \( J_i, i = 1, 2, \ldots, q \) be the Jordan blocks with various sizes, in the form of:
\[
\begin{bmatrix}
  v_i & 0 & \cdots & 0 \\
  0 & v_i & \ddots & \vdots \\
  \vdots & \ddots & \ddots & \vdots \\
  0 & \cdots & 0 & v_i \\
  \end{bmatrix}
\]
where \( v_i \) is an eigenvalue of \( S^T \). Let \( J_i = [\mu_i] \), and \( X_i \) is the \( i \)th column vector of \( X \), \( i = 1, 2, \ldots, N \). Let \( I_i \) be the size of \( J_i \) of each Jordan block, where \( i = 1, 2, \ldots, q \). We now have \( S^T = XAX^{-1} \), and therefore
\[ S^T X_i = XAX^{-1} = X_i J_i X_i^{-1} = \begin{bmatrix}
  \mu_i & 0 & \cdots & 0 \\
  0 & v_i & \ddots & \vdots \\
  \vdots & \ddots & \ddots & \vdots \\
  0 & \cdots & 0 & v_i \\
  \end{bmatrix}
\]
From the above equation, we get:
\[ S^T X_1 = v_1 X_1, \]
\[ S^T X_2 = v_2 X_2 + v_1 X_1, \]
\[ S^T X_3 = v_3 X_3 + v_2 X_2 + v_1 X_1, \]
\[ \vdots \]
\[ S^T X_{k+2} = v_1 X_k + v_2 X_{k+1} + \ldots + v_N X_N, \]
\[ S^T X_{k+3} = X_k + v_1 X_{k+2}, \]
\[ \vdots \]
Just like in Case 1, \( S^T X_1 = v_1 X_1 \), and based on the equation (7), \( v_2 z_1 X_2 = z_1^2 z_2 X_2 = z_1^2 S^T X_2 = \mu_1 z_1^2 X_2, (v_2 - \mu_1) z_1^2 X_2 = 0 \). From equation (12), \( v_1 \neq \mu_1 \). So \( z_1^2 X_2 = 0 \). Hence,
\[ Q^T = (S - z_1 e S)^T. \]
\[ Q^T X_2 = (S - z_1 e S)^T X_2 = S^T X_2 - S^T e^T z_1^2 X_2 = S^T X_2 - 0, \]
which means that \( Q^T X_2 = v_2 X_2 \). This implies that \( X_2 \) is an eigenvector of \( Q^T \) associated with the eigenvalue \( v_2 \).

From the equation \( S^T X_2 = X_2 + v_2 X_3, \) we get
\[ v_2 z_1^2 X_3 = z_1^2 v_2 X_3 = z_1^2 S^T X_3 = z_1^2 S^T X_2 - 0, \]
By equation (7), we get \( v_2 z_1^2 X_3 = (\mu z_1^2) X_3 \). Consequently, \( (v_2 - \mu_2) z_1^2 X_3 = 0 \). By equation (12), and since \( v_2 \neq \mu_2 \), we obtain \( z_1^2 X_3 = 0 \). Therefore,
\[ Q^T = (S - z_1 e S)^T, \]
\[ Q^T X_3 = (S - z_1 e S)^T X_3 = S^T X_3 - S^T e^T z_1^2 X_3 \]
\[ = S^T X_3 = X_2 + v_2 X_3, \]
Likewise, we obtain:
\[ Q^T X_2 = v_2 X_2, \]
\[ Q^T X_4 = X_3 + v_2 X_4, \]
\[ \vdots \]
\[ Q^T X_{i+2} = v_2 X_{i+2}, \]
\[ Q^T X_{i+3} = X_{i+1} + v_1 X_{i+2}, \]
\[ \vdots \]
Like in Case 1, we want to show that the set \( \{ e^T, X_2, i = 2, 3, \ldots, N \} \) is linearly independent.
Let \( Y = [e^T, X_2, \ldots, X_{N}] \).
Then, \( Q^T Y = \text{diag} [0, J_2, \ldots, J_q] \).
We now have the spectrum of \( Q \), \( \{0, v_1, \ldots, v_q\} \) which is similar to the spectrum of \( Q^T \). The spectral radius of \( Q \) is \( |v_2| \).
Therefore we get the following result:
\[ \rho(H(z_2)) = \rho \left( \frac{Q}{\mu_1} \right) = \frac{|v_2|}{|\mu_1|} < 1, \]
since \( \mu_1 > |v_2| \).

Now we can determine the convergence rate of Algorithm 1.

**Theorem 7.** Let \( A \) and \( \{z_2^{(t)}\} \) be as in Theorem 6. Then the convergence rate of the sequence \( \{z_2^{(t)}\} \) is Q-
linear, which means, there exists a vector norm $\| \|$ such that

$$\limsup_{k \to \infty} \left\| z^{(k+1)} - z_0 \right\| < 1.$$  

**Proof.** By Proposition 1, there exist an $\epsilon > 0$ and a spectral norm $\| \|$ such that $\|H'(z_0)\| \leq \rho(H'(z_0)) + \epsilon$.

By Lemma 2:

$$\|H'(z_0)\| \leq \rho(H'(z_0)) + \epsilon < 1. \tag{13}$$

Hence, by equation (6), we have $z^{(k+1)} = H'(z_0) + o(1)$, $k = 1, 2, ..., n$ and $z_0 = H'(z_0) - H'(z_0)$. Therefore, $z^{(k+1)} - z_0 = H'(z_0)(z^{(k)} - z_0) + o(1)$. From equation (13), we can get

$$\limsup_{k \to \infty} \left\| z^{(k+1)} - z_0 \right\| < 1.$$  

Therefore Algorithm 1 is Q-linear convergence.

### 5.0 CONCLUSION

Within this paper, we proved that the algorithm for finding the largest singular value of nonnegative rectangular tensors, as proposed by Zhou et al. [11], is convergent under weak irreducibility condition and has a Q-linear rate of convergence. This paper only presents the convergence properties of Algorithm 1. In regards to numerical tests, the reader can refer to the referenced studies [7, 11].

The study of rectangular tensors is relatively new. Another method for determining the largest singular value of rectangular tensors can be found in Zhang’s study [23], and it has been proven to be convergent under some assumptions. Algorithm 1 has also been generalised to nonnegative polynomials, as presented in Ibrahim’s study [24]. The method is also convergent.
